

ECED4406 – Lab #2

For Lab #2, you will analyze a password check program using power analysis.

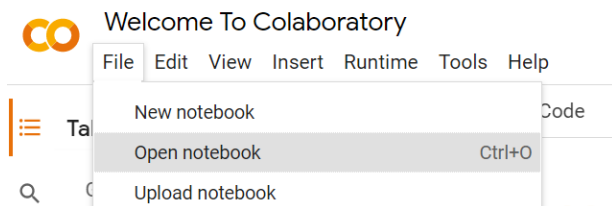

Step 1: Jupyter Introduction

We introduced Jupyter in a previous lab – for reference, see the following video:

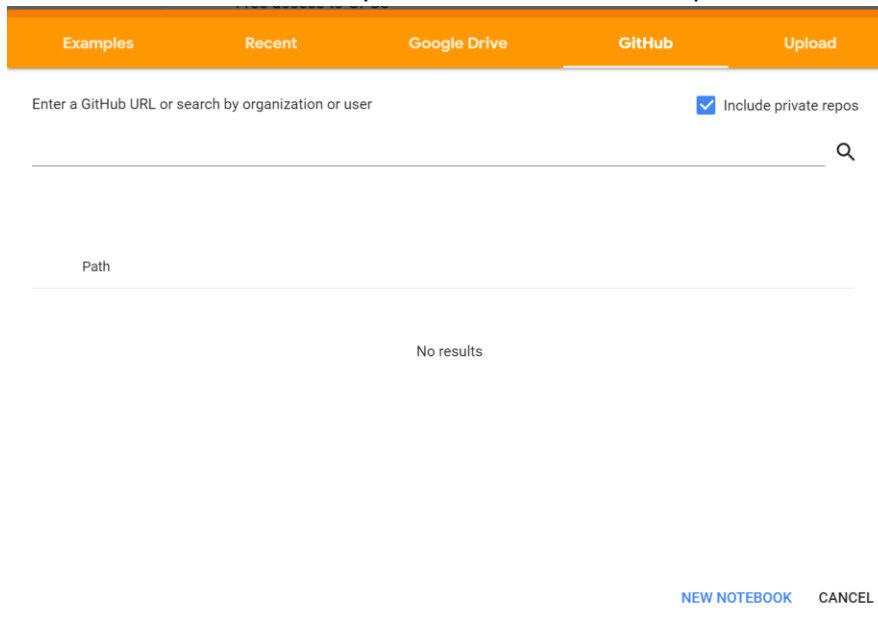

<https://www.youtube.com/watch?v=v5W8Uff4x0Q>

If you wish to use the Colab interface (requires a Google account), use the following instructions:

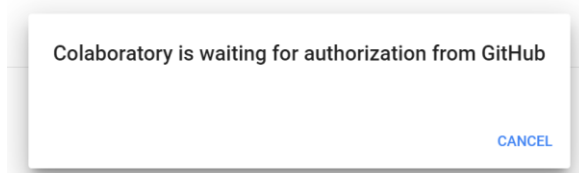

1. Select “Open Notebook”

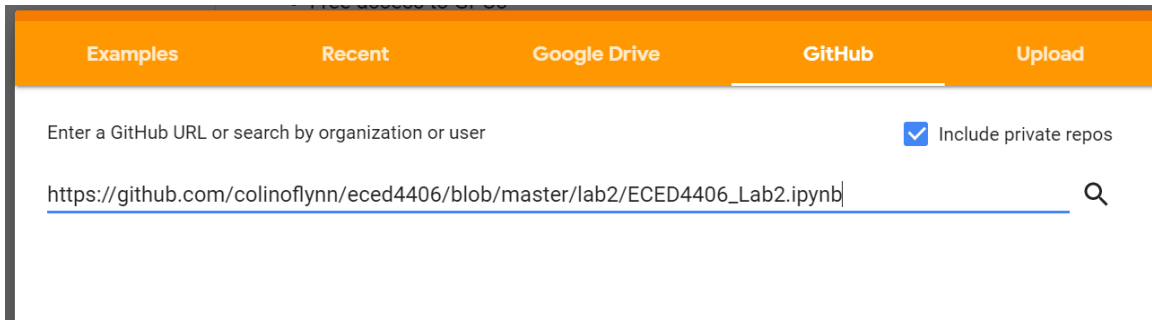

2. Go to the “GitHub” tab when you choose a notebook to open:

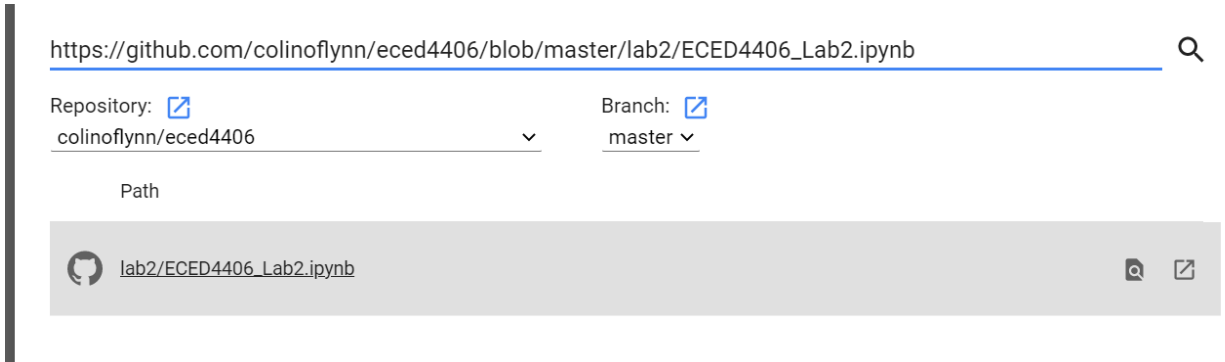

NOTE: If it asks to “Authorize with GitHub”, you can skip that. We don’t need to perform that step. Hit CANCEL and close the window that pops up.

- Copy the url **https://github.com/colinoflynn/eced4406/blob/master/lab2/ECED4406_Lab2.ipynb** into the search field, and press enter.

- Click the link in the resulting search results

- You should be rewarded with a notebook interface as shown:

ECED4406 Lab 2 - Power Analysis for Password Bypass

SUMMARY: This tutorial will introduce you to breaking devices by determining when a device is performing certain operations. Our target device will be performing a simple password check, and we will demonstrate how to perform a basic power analysis.

LEARNING OUTCOMES:

- How power can be used to determine timing information.
- Plotting multiple iterations while varying input data to find interesting locations.
- Using difference of waveforms to find interesting locations.

ChipWhisperer Tutorial Links

This tutorial will use material from the ChipWhisperer project, see the <https://github.com/newaetech/chipwhisperer-jupyter/tree/master/courses/sca101> folder. This tutorial follows tutorial 2.1B.

Note you can find the solution notebook as well there - if you get stuck on what code you should be running, see the notebook entitled 'SOLN_Lab 2_1B - Power Analysis for Password Bypass.ipynb'.

Power Trace Gathering

At this point you've got to insert code to perform the power trace capture. To keep it eas, we are going to read the data from a file. You can define the filename to use here. Note there is a test file (with a known password) and one you've got to figure it out yourself in. If you are running this on Google Colab, run the following block to download the files to your local instance:

```
[ ] %bash
wget https://github.com/colinoflynn/eced4406/raw/master/lab2/passwordtraces_known_h0px3.p
wget https://github.com/colinoflynn/eced4406/raw/master/lab2/passwordtraces_unknown.p

[ ] password_filename = "passwordtraces_known_h0px3.p" #<-- The password should be h0px3
#password_filename = "passwordtraces_unknown.p" #<-- Use this once the code works

[ ] import pickle
import random
import time
```

NOTE: You can also install Jupyter directly and run the **.ipynb** file. For many students it will be easier to run on the cloud platform.

Step 2: Lab Procedure

Building Attack

Within the lab, you'll find various "hints" about how to perform the attack. Working through these blocks, fill in the required functions:

Again, you may need to modify this a little bit such as adding code to make a new `figure()`. All the number of samples.

```
[ ] # #####
# Add your code here
# #####
raise NotImplementedError("Add your code here, and delete this.")
```

OK great - hopefully you now see one major "difference". It should look something like this:

Attack Hints

Where to find information if you can't get the right answer?

This lab is based on my ChipWhisperer labs – you can find a solution for a similar lab at http://localhost:8888/notebooks/jupyter-clear/courses/sca101/SOLN_Lab%202_1B%20-%20Power%20Analysis%20for%20Password%20Bypass.ipynb. This will be helpful in figuring out what is required at each block.

Performing Attack on Test vs Real Password Traces

There are two files in the folder - **passwordtraces_known_h0px3.p** and **passwordtraces_unknown.p**

You can use the “known” traces which have the password h0px3. The unknown password is also a 5-character password, but is a different password. Try to figure out the unknown password.

Questions to Answer [30 pts]

1. What was the unknown password? [5 pts]
2. Show a plot of a correct vs. incorrect password guess. [5 pts]
3. Can you think of a way to perform the password check without the timing problem? [5 pts]
4. Describe the program flow of your attack script. Include your software solution, making a flow-chart showing the flow, and/or bringing in some example results such as intermediate plots. [15 pts]

NOTE – The Python notebook is provided as a learning tool. You can implement your solution as a “raw” python script if you wish, or you can simply use the provided Jupyter framework. Either way, you should include snippets of your source code to demonstrate how you are detecting the differences.
